Abstract

Schismatoglottis meriraiensis P.C.Boyce & S.Y.Wong, is described from Bukit Merirai, an isolated forested Karst limestone outcrop on the Bintulu/Kapit border of N Central Sarawak. Additional to a suite of defining characteristics, *S. meriraiensis* is remarkable by possessing natural viviparous capabilities from whole, partial, and fragmentary leaves. This quality is shared with *Schismatoglottis puberulipes* Alderw. (expanded here to include *Schismatoglottis gamoandra* M. Hotta), and in a different expression (restricted to the mid-rib and terminal tubule of the blade), with *Schismatoglottis hayi* S.Y.Wong & P.C.Boyce, of the Multinervia Complex, to which *S. meriraiensis* and *S. puberulipes* are here assigned.

Introduction

Bornean Araceae display a marked degree of geological obligations, of which association with Karst limestone is the best reported (see Boyce and Wong, 2015 for a bibliography to date). In areas with spatially isolated limestone outcrops geological obligation is often associated with allopatric local endemism of individual species within clusters of related species (Ting et al., 2012; Wong, 2010; Wong and Boyce, 2011).

Here we describe a taxonomically novel locally endemic species from Bukit Merirai, an isolated forested Karst limestone outcrop on the Bintulu/Kapit border of N Central Sarawak, and most similar to two species, both limestone-restricted – *S. multinervia* M.Hotta (endemic to Mulu c. 200 km to the NE) and *S. hayi* S.Y.Wong & P.C.Boyce (Niah Caves, c. 120 km to the north) of the Multinervia Complex (Wong and Boyce, 2011).

Additional to a unique suite of defining characteristics, *S. meriraiensis* is remarkable for possessing naturally viviparous capabilities from whole, partial, and fragmentary leaves. This quality is held in common with shale-restricted Bornean *Schismatoglottis puberulipes* Alderw. (here expanded to encompass *Schismatoglottis gamoandra* M.Hotta), and shared, in a different expression (plantlets restricted to the mid-rib and terminal tubule of the blade), with *Schismatoglottis hayi*. Dimensions used in the descriptions are derived from fertile (i.e., mature) plants. Seedlings will have overall smaller measurements. In verifying geological occurrences for this paper we have been much assisted by the excellent geological map of Tate (2001).

Taxonomy

Schismatoglottis meriraiensis P.C.Boyce & S.Y.Wong, *sp. nov.*

Diagnosis: *Schismatoglottis meriraiensis* is distinguished from *S. puberulipes* by the upper surface of the leaf blades lacking raised tessellate venation, erect (vs reflexed) petioles that are about twice as long as leaf blades (vs petioles c. ¼ length of blades), and leaves erect (not arranged in a ground-hugging rosette). *Schismatoglottis meriraiensis* is readily differentiated from *S. hayi* by having the staminate flowers very tightly packed (vs somewhat lax), purple-red longitudinally ridged petioles and by lacking growth points along the distal-most portion of the leaf blade under-surface midrib.

Type: MALAYSIA (Malaysian Borneo): Sarawak: Bintulu, Bukit Merirai, 02°46'26.9"N 113°39'19.8"E, *S. Julia et al.* S.95787, July 2005, (holo: SAR!; iso: SAR – spirit preserved!).

Small herb to c. 20 cm tall, but mostly half this, vegetative tissues very weakly aromatic (terpenoids). *Stem* condensed, hypogaeal, rather stout, c. 1 cm diam. *Leaves* c. 10 together; *petiole* 3–14 cm long, rather slender, D-shaped in cross-section, stiff, longitudinally weakly ridged, red-purple, sheathing in the lower ½–2/5 (sometimes sheathing for the entire length in the leaf below an inflorescence); *wings of sheath* almost fully attached except for a blunt apical free portion c. 5 mm long, membranous, spreading, sometimes somewhat crisped, glabrous; *blade* oblong-cordate to oblong-ovoid, 8–13 cm long, 3.2–5.5 cm wide, very dark green semi glossy adaxially, noticeably paler abaxially, base narrowly but distinctly cordate with rounded posterior lobes 1–2 cm long, tip obtuse, ultimately briefly rostrate; *midrib* abaxially prominent, adaxially slightly sunken; *primary lateral veins* 11–12 on each side of the midrib, alternating with lesser interprimaries, both diverging at 70°, then rather sharply acropetally deflected before reaching the margin, adaxially somewhat prominent near the midrib; *secondary venation* arising from both the midrib and the bases of the primary veins, fine, abaxially slightly darker than surrounding tissue; *tertiary venation* forming a faint tessellate reticulum abaxially. *Inflorescence* solitary, subtended by a strongly 2-keeled stout red-purple prophyll; *peduncle* terete, very weakly longitudinally ridged, tinged red-purple where exposed, otherwise whitish. *Spathe* c. 4.5 cm long; *lower spathe* ovoid, c. 1.75 cm long, 1.3 cm wide, differentiated from the limb by a distinct constriction, glossy medium green with slightly darker longitudinal veining; *spathe limb* broadly ovate, tip apiculate, initially inflated and glossy white at onset of pistillate anthesis, then gaping and rapidly deliquescing above constriction. *Spadix* c. 4 cm long, sessile, *pistillate flower zone* somewhat conic, strongly obliquely attached to spathe/peduncle, dorsally c. 1 cm long, ventrally c. 1.5 cm long; *pistils* slightly lax, ellipsoid-globose, c. 1 mm diam., bright green; *stigma* sub-sessile, button-like, slightly more than half diameter of ovary, papillate, producing a conspicuous droplet at pistillate anthesis; *sub-pistillar staminodes* confined to a single row and a few scattered individuals around the base of the pistillate zone, tongue-shaped with the head triangular to rhomboidal, c. 1 mm wide, glossy white; *sterile interstice* c. 4 mm long, slightly narrower than top of pistillate zone, and base of staminate zone, clothed with rhomboidal staminodes, these c. 1.5 mm long, 2 mm wide at the tip, glossy white; *staminate flower zone* obconoid, c. 1.3 cm long, basally c. 4 mm diam., apically c. 6 mm diam., ivory; *stamens* very crowded, with individual flowers hardly discernible, c. 0.5 mm diam., truncate; *appendix* rather broadly ellipsoid, blunt-tipped, isodiametric with staminate zone, c. 1 cm long, 6 mm wide, ivory; *appendix staminodes* irregularly polygonal more or less flat-topped c. 0.7 mm diam. *Fruiting spathe, fruits, and seeds* not observed. Fig. 1.

Distribution and Habitat: *Schismatoglottis meriraiensis* is known only from the Type locality of Bukit Merirai, where it is highly localized. At Merirari it grows on shady ledges and in humus-filled pockets along the bases of forested limestone at elevations of c. 95 m.

Etymology: The specific epithet is combined from Latin, *ensis*, meaning ‘from’, and the known locality of Merirari, hence the *Schismatoglottis* from Merirari.

Notes: *Schismatoglottis meriraiensis* falls uncontroversially in the *Schismatoglottis* Multinervia Complex (Wong and Boyce, 2011) by the combination of vegetative tissues aromatic (terpenoids) when crushed, a fully adnate petiolar sheath, a strongly hourglass-shaped spadix, and by the 1–2 rows of large staminodes in at the junction of the pistillate zone with the spathe. Spathe limb senescence mechanics, however, of *S. meriraiensis* differs from that of *S. multinervia* and *S. hayi*, the only two species until now assigned to the Multinervia Complex, by not darkening prior to staminate anthesis and by the limb deliquescing, not splitting into recurving strips (compare Figs 1E and 2D, 2E and 3C). However, morphologically *S. puberulipes* clearly belongs to the Multinervia Complex, and has a spathe limb which deliquesces (Fig. 4G) in much the same manner as that of *S. meriraiensis*.

Production of adventitious plantlets arises in *S. meriraiensis* and *S. puberulipes* from any portions of damaged leaves (Figs 1C, 4D), whereas in *S. hayi* plantlets only arise from the distal-most portion of the mid-rib on the leaf blade undersurface (Fig. 2B). To date plantlet production has not been observed in wild *S. multiflora*, although artificial removal of leaf blades enables propagation from induced plantlets arising along the mid-veins.

The *Schismatoglottis* Multinervia Complex

The Multinervia Complex now consists of the following four species:

1. *Schismatoglottis hayi* S.Y.Wong & P.C.Boyce, *Acta Phytotaxonomica et Geobotanica* 60(3): 135–137, Fig. 2 (2011).

Type: Malaysia (Malaysian Borneo): Sarawak: Miri, Niah National Park, Batu Niah, A. Hay & al. 9369 5 Feb 1994, ex Cult. RBG Sydney, Acc. No. 940520 sub. C. *Herscovitch s.n.* (holo: K!; iso: KEP!, L!, NSW, SAR!, US!). Fig. 2.

Schismatoglottis puberulipes sensu A. Hay & Yuzammi, *Telopea* 9(1): 77–79, Fig. 9 (2000), *descr. p. maj. p. excl. typ. non* Aldwer. (1922).

2. *Schismatoglottis meriraiensis* P.C.Boyce & S.Y.Wong, *sp. nov.* Fig. 1.

3. *Schismatoglottis multinervia* M.Hotta, *Memoirs of the College of Science, University of Kyoto, ser. B*, 32 (1966) 237, Fig. 6G–N; A. Hay and Yuzammi, *Telopea* 9(1): 72–73 (2000); S.Y.Wong & P.C.Boyce, *Acta Phytotaxonomica et Geobotanica* 60(3): 132–135, Fig. 1 (2011).

Type: Malaysia (Malaysian Borneo): Sarawak: Marudi, at foot of Gunung Mulu, along Sg. Payau, M. Hotta 15297, 22 Mar 1964 (holo KYO!). Fig. 3.

4. *Schismatoglottis puberulipes* Alderw., *Bull. Jard. Bot. Buitenzorg* III, 4: 200 (1922).

Type: 'Borneo', Cult. Hort. Bogor, XI.B.X.118, C.R.W.K. van Alderwerelt van Rosenburgh 286 (lecto: BOKR! + BO spirit!; lectotype selected by Hay & Yuzammi 2000). Fig. 4

Schismatoglottis gamoandra M.Hotta, *Memoirs of the College of Science, University of Kyoto, ser. B*, 32: 237, Fig. 7A–G (1966), A. Hay and Yuzammi, *Telopea* 9(1): 123–124 (2000); P.C. Boyce, *Sarawak Museum Journal* 66 (87, n.s.): 350–352, Pl. VIII (2009), *syn. nov.*

Type: Malaysia (Malaysian Borneo): Sarawak: Bintulu ('4th Divn'), along Sg. Latai, small branch of Ulu Sg. Kakus, M. Hirano & M. Hotta 817, 7 Nov 1963 (holo: KYO!).

Notes: Alderwerelt's *Schismatoglottis puberulipes* is without doubt identical with Hotta's later *S. gamoandra*, and has nomenclatural priority (Alderwerelt 1922 vs Hotta 1966), notwithstanding that *S. puberulipes* is established upon fragmentary (but nonetheless identifiable) herbarium material from a cultivated plant of imprecise origin.

Key to the *Schismatoglottis* Multinervia Complex

- 1a. Spathe limb darkening prior to staminate anthesis, splitting into recurving strips during staminate anthesis; staminate flowers lax..... 2
- 1a. Spathe limb not darkening prior to staminate anthesis, deliquescing during staminate anthesis; staminate flowers very densely packed 3
- 2a. Leaf blade broadly ovate, up to 15 cm long, 10 cm wide, abaxially glaucescent, with tertiary venation forming a rather indistinct tessellate reticulum, never forming adventitious plantlets; spadix with interstice staminodes short, mushroom-shaped. Lithophytic on limestone, rarely terrestrial on clay but even then limestone associated, Gunung Mulu National Park, Sarawak..... *S. multinervia*
- 2b. Leaf blade oblong-lanceolate, 8–14 cm long, 3.2–5.5 cm wide, abaxially green with tertiary venation forming a conspicuous tessellate reticulum, often with adventitious plants present; spadix with interstice staminodes conspicuously elongate-cuneate, c. 3.5 mm long. Lithophytic on limestone, Niah National Park, Sarawak *S. hayi*
- 3a. Leaves in a ground-hugging rosette; tertiary venation adaxially forming a conspicuous raised tessellate reticulum. On shales and shale-derived clays in the Rejang Basin and adjacent N Kalimantan *S. puberulipes*
- 3b. Leaves erect; tertiary venation adaxially obscure. Lithophytic on limestone, Bukit Merirai.....*S. meriraiensis*

Fig. 2. *Schismatoglottis hayi* S.Y.Wong & P.C.Boyce. A, plants in habitat; B, adventitious plantlets on the tip of the leaf blade; C, inflorescence just prior to anthesis; D, inflorescence at onset of pistillate anthesis (note that the spathe limb had opened, darkened, and begun to split); E, inflorescence at male anthesis (the spathe is beginning to deliquesce and turn glossy, note the clearly visible pubescent petioles); F, spadix at staminate anthesis with the spathe artificially removed (note that the interstice staminodes are long and have flat tops, the distal part of the staminate zone is narrower than the base of the appendix, and that the appendix is pointed). A–F from AR-1880. Images © P.C. Boyce.

Fig. 3. *Schismatoglottis multinervia* M.Hotta. **A**, plants in habitat; **B**, inflorescence at onset pistillate anthesis (note the small gap that is created by the expansion of the spathe limb); **C**, inflorescence at onset of staminate anthesis, the spathe limb has expanded and split longitudinally, at the same time darkening, and the pubescent petiole is clearly visible; **D**, spadix at pistillate anthesis with the spathe artificially removed (note that the interstice staminodes are short and have rounded tops, the distal part of the staminate zone is the same diameter at the base of the appendix, and the appendix is blunt). **A–D** from AR-1932. Images © P.C. Boyce.

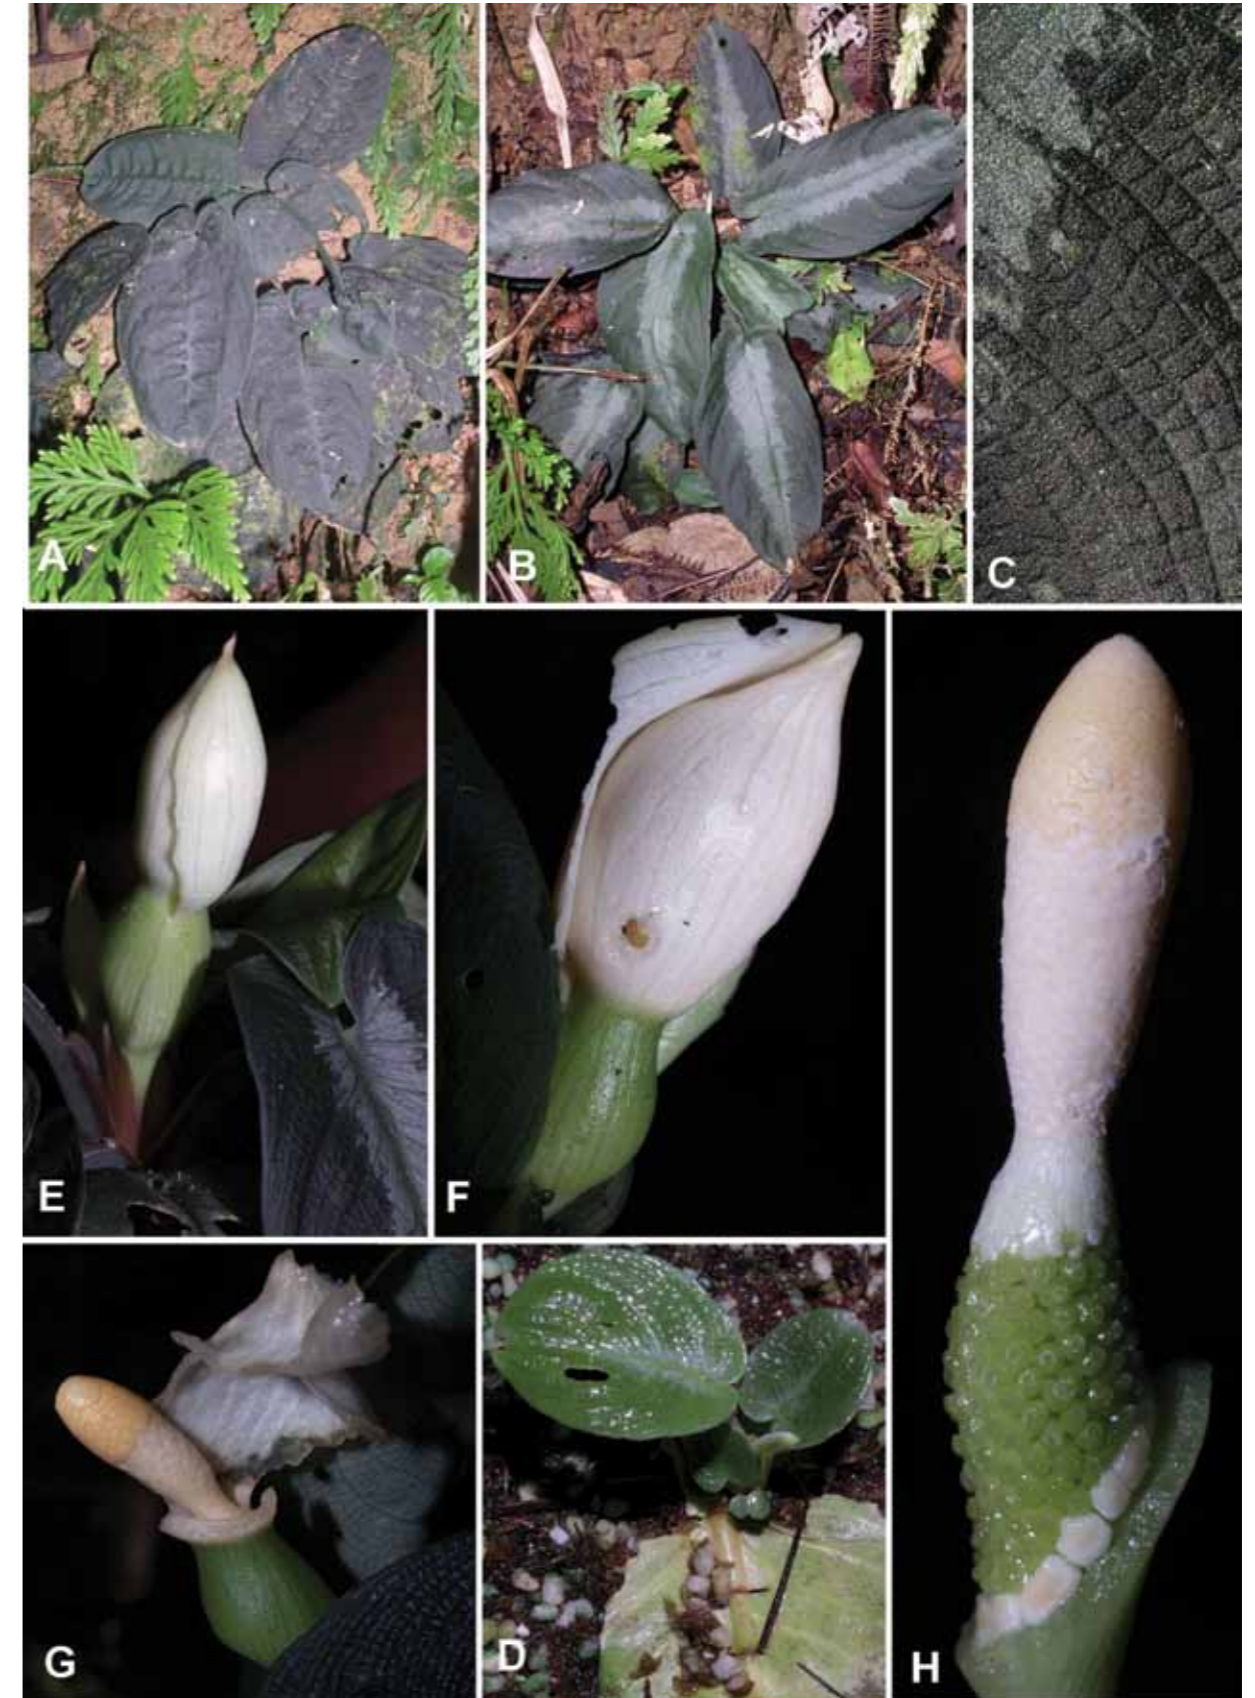

Fig. 4. *Schismatoglottis puberulipes* Alderw. **A, B**, plants in habitat to show leaf colour variation; **C**, detail of tessellate tertiary venation; **D**, adventitious plantlet arising from a damaged portion of leaf blade; **E**, inflorescence at pistillate anthesis; **F**, inflorescence near end of pistillate anthesis; **G**, inflorescence at staminate anthesis (note spathe limb deliquescing at limb/lower spathe junction); **H**, spadix at pistillate anthesis (note spathe artificially removed). **A, B** from AR-1062; **C–H** from AR-802.
